(57) **ABSTRACT**

An interface for receiving data from an image sensor having
an imaging array and a clock generator and for transferring
the data to a processor system is described. The interface
comprises a memory for storing the imaging array data and
the clocking signals at a rate determined by the clocking
signals. In response to the quantity of data in the memory, a
signal generator generates a signal for transmission to the
processor system and a circuit controls the transfer of the
data from the memory at a rate determined by the processor
system. The memory may be a first-in first-out (FIFO) buffer
or an addressable memory. The interface is preferably inte-
grated on the same die as the image sensor. The signal
generator may generate either an interrupt signal for trans-
mission to the processor system or a bus request signal for
transmission to a bus arbitration unit for the processor
system.

HOST INTERFACE FOR IMAGING ARRAYS

This application claims the benefit of U.S. Provisional Patent Application Ser. No. 60/177,496 filed on Jan. 21, 2000.

FIELD OF THE INVENTION

The invention relates generally to integrated electronic image sensing circuitry and more particularly to CMOS imaging circuitry.

BACKGROUND OF THE INVENTION

Integrated circuit (IC) technology, applied to imaging, is revolutionizing that field. Semiconductors can be used to represent an image as an electrical signal. Charge coupled devices (CCDs) are the most significant commercial IC technology to date. However, when compared with CMOS technology, there are many advantages to producing CMOS image devices.

CMOS is a less expensive technology; CMOS employs fewer mask layers and is a more mature fabrication technology with greater commercial volume. CCD technology complexity causes lower fabrication yield. One of the main benefits of employing CMOS technology, compared to CCD, is the ability to include image-processing elements on the same substrate as the imaging circuitry.

On a monolithic semiconductor IC, with a surface coincident to an optical focal plane, photosensitive elements are employed in pixels that are arranged in an array of rows and columns. The basis for the pixels of CMOS technology is a photosensitive diode. In an active pixel arrangement each pixel photodiode is buffered from the shared readout components by an amplification stage.

IC image sensors of existing technologies provide video style output. In one example, such a sensor receives master clock input. The sensor derives data sample, line, and clocks from this master clock. These clocks, which correspond to pixel, row, and column, control the sampling rate of the imaging array. The pixel data of such a sensor is output at the same rate as it is sampled. The derived clocks are output as well to synchronize the data output. The result is a stream of synchronized pixel intensities comprising a video frame.

This output is incompatible with the data interface of commercial microprocessors, without the use of additional glue logic. A commercial microprocessor data interface consists of address and control output signals and data input/output signals. This configuration allows the processor to randomly access any word of data in memory by asserting various addresses.

In an image acquiring computer system based on such a sensor and such a processor, additional interface circuitry to respond to the sensor clock outputs to sample the video information, and to make this video data available in the memory space of the processor. Optionally, this interface circuit may include interrupt signals to the processor, and enough memory space for a number of pixels.

Such additional circuitry diminishes the benefit of a single substrate that integrates sensor and processing elements. The CMOS technology optimum cost benefit is not reached.

Therefore, there is a need for an interface which may be integrated with the imaging array which a system processor can access to directly receive imaging data.

SUMMARY OF THE INVENTION

This invention is directed to an interface for receiving data from an image sensor having an imaging array and a clock generator, and for transferring the data to a processor system. The interface comprises a memory for storing the imaging array data and the clocking signals at a rate determined by the clocking signals. In response to the quantity of data in the memory, a signal generator generates a signal for transmission to the processor system and a circuit controls the transfer of the data from the memory at a rate determined by the processor system. The memory may be a first-in first-out (FIFO) buffer or an addressable memory.

The signal generator may generate an interrupt signal for transmission to the processor system or a bus request signal for transmission to a bus arbitration unit for the processor system. The circuit for controlling the transfer of the data may include a command decoder for receiving address and command signals from the processor system, a configuration register for storing configuration data for the FIFO buffer and a read control for controlling the read-out of the FIFO buffer, and may further include a bus command unit for receiving control of the system bus and providing an address for the data read-out from the memory.

In accordance with another aspect of this invention, an integrated semiconductor imaging circuit for use with an electronic processing system having a data bus comprises an imaging array sensor having an array of sensing pixels and an array address generator integrated on a die and an interface integrated on the same die. The interface is adapted to receive data from the imaging array sensor as determined by the imaging array and to transfer the data to the electronic processing system as determined by the electronic processing system. The interface may include a memory such as a FIFO buffer or an addressable memory for storing imaging array data and address signals at a rate determined by the imaging array sensor, and a circuit for controlling the transfer of the data from the memory means to the data bus at a rate determined by the electronic processing system. The imaging circuit may further include a bus arbitration circuit integrated on the same die and coupled to the circuit for controlling the transfer of the data.

In accordance with a further aspect of this invention, an integrated semiconductor imaging circuit for use with an electronic processing system having a data bus may comprise an imaging array of sensing pixels, a buffer for storing data received at an input port and for outputting data through an output port to the data bus, a circuit for transferring data from a selected pixel to the buffer input port, a circuit for determining the quantity of data in the buffer, a circuit for alerting the electronic processing system when the quantity of data in the buffer attains a predetermined level and a controller adapted to respond to the electronic processing system for controlling the transfer of the stored data through the buffer output port.

In accordance with another aspect of this invention, an integrated semiconductor imaging circuit for use with an electronic processing system having a data bus and a system address/control bus, may comprise an imaging array of sensing pixels, a buffer for storing data received at an input port and for outputting data through an output port to the data bus, a circuit for transferring data from a selected pixel to the buffer input port, a circuit for determining the quantity of data in the buffer, a controller for seeking control of the data bus when the quantity of data in the buffer attains a predetermined level and adapted to respond to the availability of the data bus for controlling the transfer of the stored

3

data through the buffer output port. The integrated semiconductor imaging circuit may further include a bus arbitration unit for receiving data bus control requests and for providing data bus control in response to a request, and the controller for receiving bus control comprising a register for storing and incrementing destination addresses, and a circuit for asserting the destination address and write controls on the system address/control bus.

In accordance with a further aspect of this invention, an integrated semiconductor imaging circuit for use with an electronic processing system having a data bus, may comprise an imaging array of sensing pixels, an addressable memory having a plurality of memory cells arranged in rows and columns for storing data received at an input port and for outputting data through an output port to the data bus, a circuit for transferring data from a selected pixel to a selected memory cell through the memory input port, a circuit for determining the quantity of data in the memory, a circuit for alerting the electronic processing system when the quantity of data in the memory attains a predetermined level, and a controller adapted to respond to the electronic processing system for controlling the transfer of the stored data through the memory output port.

In accordance with another aspect of this invention, an integrated semiconductor imaging circuit for use with an electronic processing system having a data bus and a system address/control bus, may comprise an imaging array of sensing pixels, an addressable memory having a plurality of memory cells arranged in rows and columns for storing data received at an input port and for outputting data through an output port to the data bus, a circuit for transferring data from a selected pixel to a selected memory cell through the memory input port, a circuit for determining the quantity of data in the memory, and a controller for seeking control of the data bus when the quantity of data in the memory attains a predetermined level and adapted to respond to the availability of the data bus for controlling the transfer of the stored data through the memory output port. The integrated semiconductor imaging circuit may further include a bus arbitration unit for receiving data bus control requests and for providing data bus control in response to a request, and the controller for receiving bus control comprising a register for storing and incrementing destination addresses, and a circuit for asserting the destination address and write controls on the system address/control bus.

Other aspects and advantages of the invention, as well as the structure and operation of various embodiments of the invention, will become apparent to those ordinarily skilled in the art upon review of the following description of the invention in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be described with reference to the accompanying drawings, wherein:

FIG. 1 is a block diagram of a computer system utilizing the imaging array sensor;

FIG. 2 is a block diagram of an imaging array sensor including the interface of the present invention;

FIG. 3 is a block diagram of the pixel imaging array and access;

FIG. 4 is a block diagram of the video clock and array address generator;

FIG. 5 is a block diagram of a FIFO buffer;

FIG. 6 is a block diagram of a computer system with bus arbitration utilizing the imaging array sensor;

4

FIG. 7 is a block diagram of an imaging array sensor that includes an interface having bus arbitration circuitry; and

FIG. 8 is a block diagram of an imaging array sensor that includes an interface having an addressable memory.

DETAILED DESCRIPTION OF THE INVENTION

The imaging computer system illustrated in FIG. 1 includes a central processing unit (CPU) 10, other memory and system components 11, an imaging array sensor 12, an interface 13 in accordance with the present invention and a video clock generator 14. The CPU 10, components 11 and interface 13 all have access to a system data bus 15 and are controlled by the CPU 11 via the system control and address bus 16. The clock generator 14 provides pixel clock signals C_P to the imaging array sensor 12. The interface 13 is further connected to the CPU 10 through an interrupt bus 17 by which the CPU 10 is signalled that data is available for it to upload.

In accordance with the present invention, the interface 13 stores data and clocking signals from the imaging array sensor 12 in order to free up the CPU 10 for other processing. In addition, the full economic and commercial advantage of CMOS technology may be gained by integrating the interface 13 on the same die as the imaging array sensor 12.

An embodiment of the interface 13 is illustrated as a block diagram in FIG. 2. The imaging array sensor 12 includes an imaging array 21 which is an array of active photosensitive pixels with access control as will be described further with reference to FIG. 3. The imaging array 21 further includes an array address generator 22 which generates the column addresses A_C , the row addresses A_R , the row clock C_R and the frame clock C_F as will be described further with reference to FIG. 4.

Referring to FIG. 3, the array 30 of pixels 33 is organized in rows 31 and columns 32. Each pixel 33 is located at the intersection of a row 31 and a column 32. The row control lines 34 provide access to a row 31 of pixels 33. The row line 34 is driven by the row drivers 35 in response to the row address signal A_R . Each selected pixel 33 asserts data onto its own column data line 36 when accessed. The data on lines 36 is amplified by column amplifiers and second stage amplification in unit 37. Unit 37 further selects the column 32 as determined by column address A_C from which array data D_A is placed on the array output 38.

Referring to FIG. 4, the array address generator 22 is shown in greater detail. The column address A_C is generated by a column counter 41 which is incremented by the video system clock C_P . The maximum number of sequential addresses generated by the column counter 41 will depend on the number of columns in the imaging array 21, however the actual number of sequential addresses generated by the column counter 41 will be determined by the column boundary signal B_C which is controlled by the CPU 10 as will be described later. The row clock C_R is generated by the overflow of the column counter 41. The row counter 42 generates the row address signal A_R based on the row clock signal C_R and the row boundary signal B_R . The maximum number of sequential addresses generated by the row counter 42 will depend on the number of rows in the imaging array 21, however the actual number of sequential addresses generated by the row counter 42 will be determined by the row boundary signal B_R which is controlled by the CPU 10 as will be described later. The row clock C_R is also applied

5

to an output 43 from the array address generator 22. The row counter 42 also generates a frame signal C_F based on count overflow.

Referring again to FIG. 2, the interface 13 includes a memory 44 as well as devices 45 to 49 required to support the memory 44. In this particular embodiment, memory 44 is a first-in first-out (FIFO) buffer memory. FIFO buffer 44 receives array data D_A from the imaging array, clocking signals C_P from the video clock generator 14 and clocking signals C_R and C_F from the array address generator 22. FIFO buffer 44 is shown in greater detail in FIG. 5. The imaging array 21 output D_A , row clock C_R and frame clock C_F are bundled onto a single bus 51 for storage in the buffer 44. The storage components of the FIFO buffer 44 are registers 52 arranged as a shift register series 53. Since the total number of valid outputs may vary due to the differing rates of storage and access, the bus 51 is connected to each register 52. An increment/decrement counter 54 is used to count the occurrences of FIFO buffer 44 writes and FIFO buffer 44 reads. Counter 54 has access to the pixel clock C_P and a FIFO read signal S_R . The FIFO counter 54 output S_C is applied to buffer output 55 and to the Register address decoder 56. The decoder uses the counter output S_C and pixel clock C_P in determining when to assert the appropriate register write signal on lines 57. The read signal S_R is connected to the shift registers 52 to shift the registers by a number of registers depending on the read signal S_R value. The same number of registers, from the end of the buffer, asserts data D_I on the system data bus 15 during this operation.

There are basically three types of FIFO buffers, each of which may be used with the present invention. The first type of buffer 44 is the one shown in FIG. 5 where stored data is removed from buffer register series 53 from the first register 53 on the right hand end and data from the bus 51 is written into the last available shift register 52 from the left end of the buffer register series 53. A second type of buffer is one where the data is written into the first register on the left hand end of the buffer register series and data is taken out of the buffer register series from the first register with data in the series looking at it from the right end of the register series. The third type of buffer is one in which data from the data bus is written into the last available shift register looking from the left end of the buffer register series and data is taken out of the buffer register series from the first register with data in the series looking at it from the right end of the register series. In all three cases, data is removed from the buffer in the same sequence that it is entered into the buffer.

Referring again to FIG. 2, the interface 13 includes devices 45 to 49 to support the FIFO buffer 44. The devices include a Chip Command Decoder 45, FIFO Configuration Registers 46, FIFO Read Control, an Interrupt Generator 48 and Array Registers 49.

The CPU 10 accesses the registers 46 and 49 and FIFO buffer 44 through the Chip Command Decoder 45 by asserting the necessary read or write commands, along with the address on the system address and command bus 16. The command decoder 45 identifies any buffer or register being addressed and asserts the necessary read or write signal on the FIFO read control 47 line 56, the FIFO configuration register 46 command bus 57, or the array register 49 command bus 58. The signal on line 56 permits the FIFO read control 47 to generate a FIFO read signal S_R in response to the output bus width signal S_{BW} . Variation of the FIFO 44 output bus width register provides compatibility with a variety of system bus configurations such as 8-bit or 32-bit.

The FIFO configuration registers 46 include the FIFO output bus width, the FIFO limit value, the FIFO interrupt

6

mask, and the FIFO interrupt register. All of these registers are connected to the system data bus 15 and are read/write capable, except the FIFO interrupt register, which is read only and determines its value from the interrupt generator as signal S_I . The reading and writing of these registers is controlled by the FIFO register command bus 57. The output of the FIFO configuration registers include FIFO limit signal S_L from the FIFO limit register, the interrupt enable signal S_E from the FIFO interrupt mask, and the output bus width signal S_{BW} from the FIFO output bus width register.

The interrupt generator 48 compares the FIFO counter output S_C and the FIFO limit S_L . If $S_C \geq S_L$ and if the interrupt enable signal S_E is valid, the generator 48 asserts the interrupt signal S_I to the CPU 10 via the interrupt bus 17. The use of an interrupt signal S_I as an interrupt to the CPU 10 allows the processor to multi-task. It performs a buffer 44 unload operation when the interrupt is asserted, and carries out other programmed tasks at all other times.

Access to the array registers 49 is controlled by the array register command bus, 58. Data is exchanged with the system data bus 15. The content of the registers 49 defines the number of rows and columns to be employed in the imaging array 21. This information is communicated to the array address generator 22 by the row and column boundary signals B_R and B_C .

The above interface 13 signals the CPU 10 through the interrupt signal S_I when it has an amount of data approaching the limits of its storage capacity. The CPU then responds by having the data downloaded onto the system bus 15. It is important for the CPU to respond to the interface faster than the imaging array 21 can generate data. In addition, the size of the FIFO buffer 44 will also depend on the latency of the CPU 10, since during the period of time required by the CPU 10 to respond to the interrupt signal S_I , data is being stored in the buffer 44. The faster that the CPU 10 is able to respond to the interrupt and accept the downloaded data, the smaller the buffer 44 can be and the less space that it will require if integrated on the die with the imaging array 21. However, in real time control applications, it is important that the interface 13 and the CPU 10 be matched so that the data from all frames scanned by the imaging array 21 is properly and completely transferred to the CPU 10. This requirement may be relaxed somewhat for camera type applications where the necessity of capturing all frames is not required.

In a further embodiment of the present invention as illustrated in FIG. 6, the interface 73 would interact with the CPU 10 and other system components through a bus arbitration unit 61. Rather than send an interrupt signal S_I to the CPU 10, the interface 73 sends a bus request signal S_{BR} to the bus arbitration unit 61 and receives an arbitration acknowledgement signal S_{AA} when the bus 15 is available to it for downloading data. As illustrated in FIG. 6, the other units, CPU 10 and components 11 in the system have their own arbitration request lines 62 and arbitration acknowledgement lines 63. The Bus Arbitration Unit 61 receives all the requests for the bus 15 and selects one unit that is acknowledged as the current bus master.

The required components in the interface 73 that are required in order for it to be compatible with a bus arbitration system are shown in FIG. 7. A Bus Request Generator 64 functions in the same manner as the Interrupt Generator 48 shown in FIG. 2. A bus request signal S_{BR} is generated in the same manner as the interrupt S_I . If $S_C \geq S_L$ and the bus request enable signal S_{BE} is valid, the generator 64 asserts the bus request signal S_{BR} to the bus arbitration unit 61.

An arbitration acknowledge signal S_{AA} notifies the interface 73 that the interface 73 may assert command of the bus

15. The arbitration acknowledge signal S_{AA} is applied to the chip command decoder **45** and a bus command unit **65**. The arbitration acknowledge signal S_{AA} deactivates the command decoder **45** for the duration that the interface controls the bus **15**. On receiving the arbitration acknowledge signal S_{AA} , the bus command unit **65** will activate an output address unit **66** via the request output address signal S_{AR} and receive from it the next address on the output address signal S_{AN} . This address is sent out onto the system address and control line **16**. At the same time the bus command unit **65** asserts the necessary read or write signal on the FIFO read control **47** line **67**.

The address may represent a location in the CPU **10**, however, one advantage of this arrangement is that the address may be to a location in one of the system components **11** such as a memory so that the data may be stored in the system for processing by the CPU **10** without the CPU **10** being disturbed to make the transfer. The output address unit **66** contains a register and increment circuit for the purpose of recording and updating this address. The addresses in the output address unit **66** are transferred to the address registers through bus **15** under the control of a signal from CPU **10** on the system control and address bus **16** through command decoder **45**.

As stated previously, the imaging array sensor **12** and the interface may be integrated onto one die. However, in addition, the Bus Arbitration Unit **61** may also be integrated onto the same die, and thus the bus arbitration request and acknowledge signals on lines **62** and **63** become external signals of the integrated unit.

In a further embodiment of the present invention, the memory in the interface **83** may be an addressable memory **81** as shown on FIG. **8**. For purposes of writing to memory **81** from the imaging array **21** the row and frame clocks C_R and C_F serve as row and column addresses. The video system clock C_P serves as a write clock. Thus the memory **81** records the imaging array output D_A at the same rate as the imaging array **21**, and in the same array order as the imaging array **21**.

For reading purposes, the read control signal S_R provides the necessary address information, bus width information and read control timing. The memory read control **82** derives this information from the memory configuration registers **84** via the output bus width signal S_{BW} and from the command decoder **45** via the read enable and read address bus **16** and through line **85**. The memory configuration registers **84** are identical to the FIFO configuration registers **46**. The memory **81** also includes an increment/decrement counter similar to counter **54** to interface with the interrupt generator **48**. In addition, the interface **83** may be adapted for use with a bus arbitration unit **61** in the same manner that the interface **73** has been adapted as described in conjunction with FIG. **7**.

Though the use of an addressable memory **81** in interface **83** does not provide the size, simplicity and lower cost of a FIFO memory, the fact that the memory is addressable allows the CPU to select parts or patterns from each frame for processing though the memory **81** would normally hold one frame which would be refreshed with each scan.

While the invention has been described according to what is presently considered to be the most practical and preferred embodiments, it must be understood that the invention is not limited to the disclosed embodiments. Those ordinarily skilled in the art will understand that various modifications and equivalent structures and functions may be made without departing from the spirit and scope of the invention as defined in the claims. Therefore, the invention as defined in

the claims must be accorded the broadest possible interpretation so as to encompass all such modifications and equivalent structures and functions.

What is claimed is:

1. An interface for receiving data from an image sensor having an imaging array and a clock generator for transfer to a processor system comprising:

- a memory for storing imaging array data and clocking signals at a rate determined by the clocking signals;
- a signal generator for generating a signal for transmission to the processor system in response to the quantity of data in the memory; and
- a circuit for controlling the transfer of the data from the memory at a rate determined by the processor system.

2. An interface as claimed in claim 1 wherein the memory is a first-in first-out (FIFO) buffer.

3. An interface as claimed in claim 2 wherein the signal generator generates an interrupt signal for transmission to the processor system.

4. An interface as claimed in claim 3 wherein the circuit for controlling the transfer of the data includes:

- a command decoder for receiving address and command signals from the processor system;
- a configuration register for storing configuration data for the FIFO buffer; and
- a read control for controlling the read-out of the FIFO buffer.

5. An interface as claimed in claim 4 wherein the interface further includes an array register for determining the dimension of the imaging array data.

6. An interface as claimed in claim 2 wherein the signal generator generates a bus request signal for transmission to a bus arbitration unit for the processor system.

7. An interface as claimed in claim 6 wherein the circuit for controlling the transfer of the data further includes:

- a command decoder for receiving address and command signals from the processor system;
- a configuration register storing configuration data for the FIFO buffer;
- a read control for controlling the read-out of the FIFO buffer; and
- a bus command unit for receiving control of the system bus and providing an address for the data read-out from the FIFO buffer.

8. An interface as claimed in claim 1 wherein the memory is an addressable memory.

9. An interface as claimed in claim 8 wherein the signal generator generates an interrupt signal for transmission to the processor system.

10. An interface as claimed in claim 9 wherein the circuit for controlling the transfer of the data includes:

- a command decoder for receiving address and command signals from the processor system;
- a configuration register for storing configuration data for the addressable memory; and
- a read control for controlling the read-out of the addressable memory.

11. An interface as claimed in claim 10 wherein the interface further includes an array register for determining the dimension of the imaging array data.

12. An interface as claimed in claim 8 wherein the signal generator generates a bus request signal for transmission to a bus arbitration unit for the processor system.

13. An interface as claimed in claim 12 wherein the circuit for controlling the transfer of the data further includes:

- a command decoder for receiving address and command signals from the processor system;

9

a configuration register storing configuration data for the addressable memory;
 a read control for controlling the read-out of the addressable memory; and
 a bus command unit for receiving control of the system bus and providing an address for the data read-out from the addressable memory.

14. An interface as claimed in claim **13** wherein the interface further includes an array register for determining the dimension of the imaging array data.

15. An integrated semiconductor imaging circuit for use with an electronic processing system having a data bus comprising:

an imaging array sensor having an array of sensing pixels and an array address generator integrated on a die; and
 an interface integrated on the die for receiving data from the imaging array sensor as determined by the imaging array sensor and adapted to transfer the data to the electronic processing system as determined by the electronic processing system, the interface including:
 a memory for storing imaging array data and address signals at a rate determined by the imaging array sensor; and
 a circuit for controlling the transfer of the data from the memory to the data bus at a rate determined by the electronic processing system.

10

16. An integrated semiconductor imaging circuit as claimed in claim **15** wherein the memory includes a first-in first-out (FIFO) buffer.

17. An integrated semiconductor imaging circuit as claimed in claim **16** which further includes a bus arbitration unit coupled to the circuit for controlling the transfer of the data.

18. An integrated semiconductor imaging circuit as claimed in claim **16** which further includes a bus arbitration unit integrated on the die and coupled to the circuit for controlling the transfer of the data.

19. An integrated semiconductor imaging circuit as claimed in claim **16** wherein the memory includes an addressable memory.

20. An integrated semiconductor imaging circuit as claimed in claim **19** which further includes a bus arbitration unit coupled to the circuit for controlling the transfer of the data.

21. An integrated semiconductor imaging circuit as claimed in claim **19** which further includes a bus arbitration unit integrated on the die and coupled to the circuit for controlling the transfer of the data.

UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 6,972,790 B2
DATED : December 6, 2005
INVENTOR(S) : Mark Suska

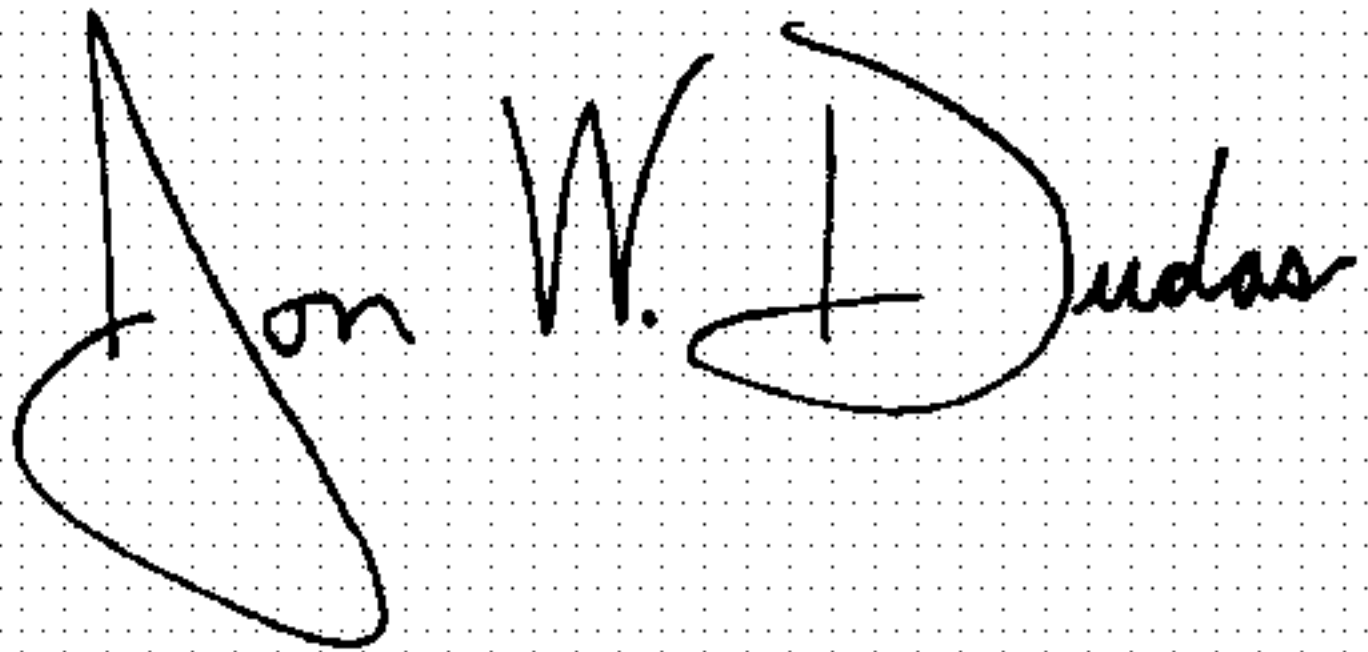

Page 1 of 1

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Column 10,
Line 2, after "claim", delete "16" and insert -- 15 --.

Signed and Sealed this

Thirtieth Day of May, 2006

A handwritten signature in black ink on a light gray dotted background. The signature reads "Jon W. Dudas" in a cursive, stylized script. The "J" is large and loops around the "on". The "W" is formed by two connected 'v' shapes. The "D" is a large, open loop, and "udas" follows in a smaller, more regular script.

JON W. DUDAS

Director of the United States Patent and Trademark Office

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Column 10,

Line 14, after "claim", delete "16" and insert --15 --.

This certificate supersedes Certificate of Correction issued May 30, 2006.

Signed and Sealed this

Twenty-fifth Day of December, 2007

A handwritten signature in black ink, reading "Jon W. Dudas". The signature is stylized, with a large, looped initial "J" and a cursive "Dudas".
